Regression and Classification with R †

- ▶ Basics of regression and classification
- ▶ Building a linear regression model to predict CPI data
- ▶ Building a generalized linear model (GLM)
- ▶ Building decision trees with package *party* and *rpart*
- ▶ Training a random forest model with package *randomForest*

†Chapter 4: Decision Trees and Random Forest & Chapter 5: Regression, in book *R and Data Mining: Examples and Case Studies*.

<http://www.rdatamining.com/docs/RDataMining-book.pdf>

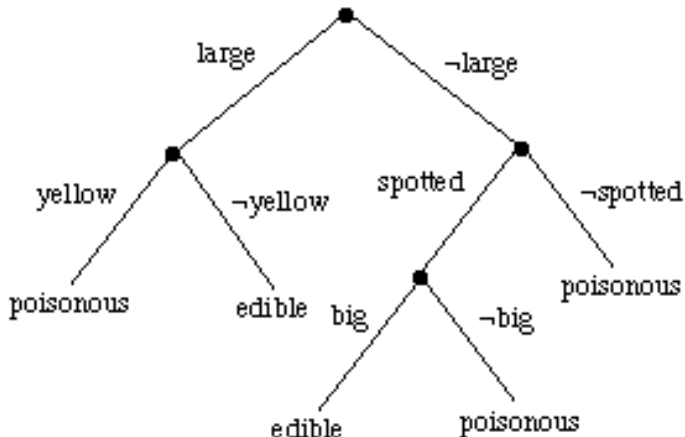

Regression and Classification

- ▶ Regression: to predict a continuous value, such as the volume of rain
- ▶ Classification: to predict a categorical class label, such as weather: rainy, sunny, cloudy or snowy

Regression

- ▶ Regression is to build a function of *independent variables* (also known as *predictors*) to predict a *dependent variable* (also called *response*).
- ▶ For example, banks assess the risk of home-loan applicants based on their age, income, expenses, occupation, number of dependents, total credit limit, etc.
- ▶ Linear regression models
- ▶ Generalized linear models (GLM)

An Example of Decision Tree

Edible Mushroom decision tree[‡]

[‡]<http://users.cs.cf.ac.uk/Dave.Marshall/AI2/node147.html>

Random Forest

- ▶ Ensemble learning with many decision trees
- ▶ Each tree is trained with a random sample of the training dataset and on a randomly chosen subspace.
- ▶ The final prediction result is derived from the predictions of all individual trees, with mean (for regression) or majority voting (for classification).
- ▶ Better performance and less likely to overfit than a single decision tree, but with less interpretability

Regression Evaluation

- ▶ MAE: Mean Absolute Error

$$\text{MAE} = \frac{1}{n} \sum_{i=1}^n |\hat{y}_i - y_i| \quad (1)$$

- ▶ MSE: Mean Squared Error

$$\text{MSE} = \frac{1}{n} \sum_{i=1}^n (\hat{y}_i - y_i)^2 \quad (2)$$

- ▶ RMSE: Root Mean Squared Error

$$\text{RMSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (\hat{y}_i - y_i)^2} \quad (3)$$

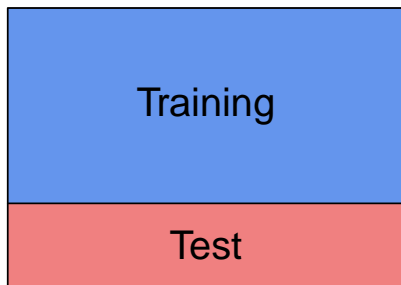

where y_i is actual value and \hat{y}_i is predicted value.

Overfitting

- ▶ A model is over complex and performs very well on training data but poorly on unseen data.
- ▶ To evaluate models with out-of-sample test data, i.e., data that are not included in training data

Training and Test

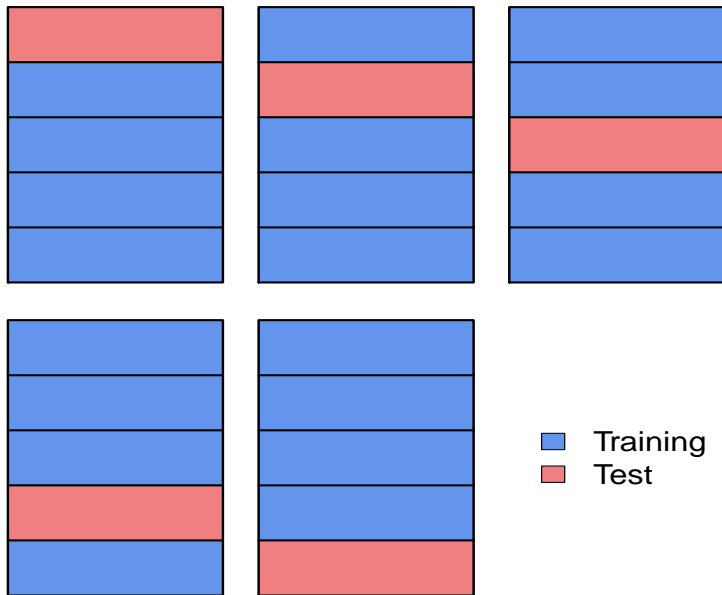

- ▶ Randomly split into training and test sets
- ▶ 80/20, 70/30, 60/40 ...

k -Fold Cross Validation

- ▶ Split data into k subsets of equal size
- ▶ Reserve one set for test and use the rest for training
- ▶ Average performance of all above

An Example: 5-Fold Cross Validation

Online Resources

Linear Regression

- ▶ Linear regression is to predict response with a linear function of predictors as follows:

$$y = c_0 + c_1x_1 + c_2x_2 + \cdots + c_kx_k,$$

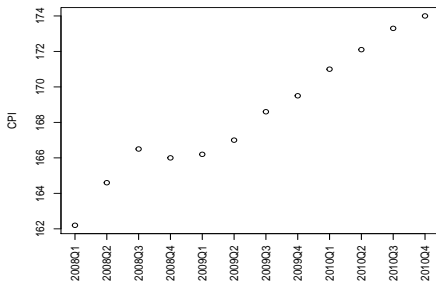

where x_1, x_2, \dots, x_k are predictors, y is the response to predict, and c_0, c_1, \dots, c_k are coefficients to learn.

- ▶ Linear regression in R: `lm()`
- ▶ The Australian Consumer Price Index (CPI) data: quarterly CPIs from 2008 to 2010 [§]

[§]From Australian Bureau of Statistics, <http://www.abs.gov.au>

The CPI Data

```
## CPI data
year <- rep(2008:2010, each = 4)
quarter <- rep(1:4, 3)
cpi <- c(162.2, 164.6, 166.5, 166.0,
         166.2, 167.0, 168.6, 169.5,
         171.0, 172.1, 173.3, 174.0)
plot(cpi, xaxt="n", ylab="CPI", xlab="")
# draw x-axis, where "las=3" makes text vertical
axis(1, labels=paste(year,quarter,sep="Q"), at=1:12, las=3)
```

Linear Regression

```
## correlation between CPI and year / quarter
cor(year, cpi)
## [1] 0.9096316

cor(quarter, cpi)
## [1] 0.3738028

## build a linear regression model with function lm()
fit <- lm(cpi ~ year + quarter)
fit
##
## Call:
## lm(formula = cpi ~ year + quarter)
##
## Coefficients:
## (Intercept)      year      quarter
## -7644.488      3.888      1.167
```

With the above linear model, CPI is calculated as

$$\text{cpi} = c_0 + c_1 * \text{year} + c_2 * \text{quarter},$$

where c_0 , c_1 and c_2 are coefficients from model fit.

What will the CPI be in 2011?

```
# make prediction
cpi2011 <- fit$coefficients[[1]] +
  fit$coefficients[[2]] * 2011 +
  fit$coefficients[[3]] * (1:4)
cpi2011
## [1] 174.4417 175.6083 176.7750 177.9417
```

With the above linear model, CPI is calculated as

$$\text{cpi} = c_0 + c_1 * \text{year} + c_2 * \text{quarter},$$

where c_0 , c_1 and c_2 are coefficients from model fit.

What will the CPI be in 2011?

```
# make prediction
cpi2011 <- fit$coefficients[[1]] +
  fit$coefficients[[2]] * 2011 +
  fit$coefficients[[3]] * (1:4)
cpi2011
## [1] 174.4417 175.6083 176.7750 177.9417
```

An easier way is to use function `predict()`.

More details of the model can be obtained with the code below.

```
## attributes of the model
attributes(fit)

## $names
## [1] "coefficients" "residuals" "effects"
## [4] "rank" "fitted.values" "assign"
## [7] "qr" "df.residual" "xlevels"
## [10] "call" "terms" "model"
##
## $class
## [1] "lm"

fit$coefficients
## (Intercept) year quarter
## -7644.487500 3.887500 1.166667
```

Function residuals(): differences btw observed & fitted values

```
## differences between observed values and fitted values
```

```
residuals(fit)
```

```
##           1           2           3           4           5
## -0.57916667  0.65416667  1.38750000 -0.27916667 -0.46666667
##           6           7           8           9          10
## -0.83333333 -0.40000000 -0.66666667  0.44583333  0.37916667
##          11          12
##  0.41250000 -0.05416667
```

```
summary(fit)
```

```
##
```

```
## Call:
```

```
## lm(formula = cpi ~ year + quarter)
```

```
##
```

```
## Residuals:
```

```
##      Min       1Q   Median       3Q      Max
## -0.8333 -0.4948 -0.1667  0.4208  1.3875
```

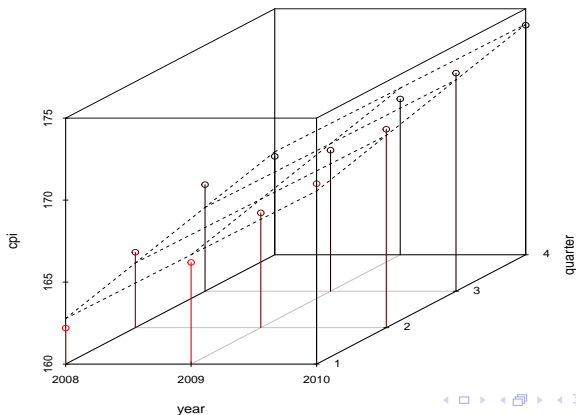

```
##
```

```
## Coefficients:
```

```
##              Estimate Std. Error t value Pr(>|t|)
## (Intercept) -7644.4875   518.6543  -14.739 1.31e-07 ***
## year          3.8875     0.2582   15.058 1.09e-07 ***
## quarter      1.1667     0.1885    6.188 0.000161 ***
```

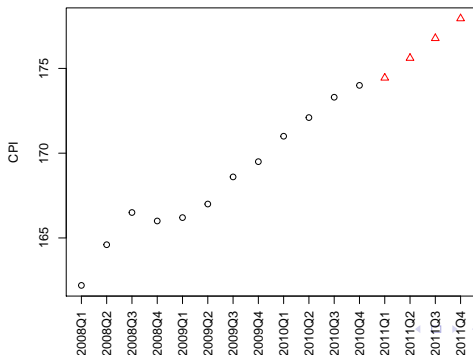

3D Plot of the Fitted Model

```
library(scatterplot3d)
s3d <- scatterplot3d(year, quarter, cpi, highlight.3d=T, type="h",
  lab=c(2,3)) # lab: number of tickmarks on x-/y-axes
s3d$plane3d(fit) # draws the fitted plane
```

Prediction of CPIs in 2011

```
data2011 <- data.frame(year=2011, quarter=1:4)
cpi2011 <- predict(fit, newdata=data2011)
style <- c(rep(1,12), rep(2,4))
plot(c(cpi, cpi2011), xaxt="n", ylab="CPI", xlab="",
      pch=style, col=style)
txt <- c(paste(year,quarter,sep="Q"),
         "2011Q1", "2011Q2", "2011Q3", "2011Q4")
axis(1, at=1:16, las=3, labels=txt)
```

Generalized Linear Model (GLM)

- ▶ Generalizes linear regression by allowing the linear model to be related to the response variable via a link function and allowing the magnitude of the variance of each measurement to be a function of its predicted value
- ▶ Unifies various other statistical models, including linear regression, logistic regression and Poisson regression
- ▶ Function `glm()`: fits generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution

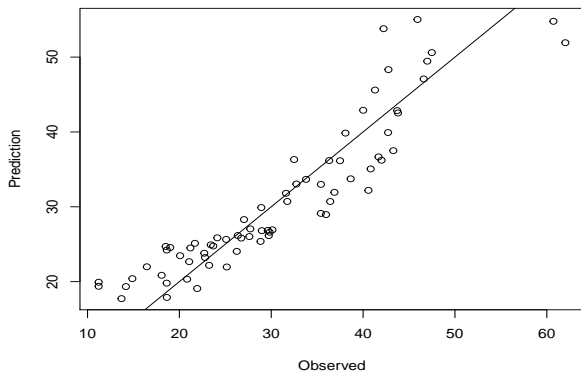

Build a Generalized Linear Model

```
## build a regression model
data("bodyfat", package="TH.data")
myFormula <- DEXfat ~ age + waistcirc + hipcirc + elbowbreadth +
  kneebreadth
bodyfat.glm <- glm(myFormula, family=gaussian("log"), data=bodyfat)
summary(bodyfat.glm)

##
## Call:
## glm(formula = myFormula, family = gaussian("log"), data = b...
##
## Deviance Residuals:
##      Min       1Q   Median       3Q      Max
## -11.5688  -3.0065   0.1266   2.8310  10.0966
##
## Coefficients:
##              Estimate Std. Error t value Pr(>|t|)
## (Intercept)  0.734293   0.308949   2.377  0.02042 *
## age          0.002129   0.001446   1.473  0.14560
